What is Prostate Cancer?
The prostate gland is a walnut-shaped gland that sits below the bladder. The prostate surrounds the urethra, the tube that carries urine out of your body.

Pelvis Anatomy for People with Prostates

Prostate cancer is when abnormal cells in your prostate grow out of control. Prostate cancer cells can form a tumor in your gland and spread by breaking away from the tumor. They can travel through blood vessels or lymph vessels to reach other parts of the body. After spreading, cancer cells may attach to other organs and tissues and grow to form new tumors, causing damage where they land.

Other Conditions of the Prostate
• Enlarged Prostate or Benign Prostatic Hyperplasia (BPH) is a condition where the prostate becomes large and starts to cause urinary and other problems.

• Prostatitis and Chronic Pelvic Pain are conditions that cause inflammation in the prostate and pain around the penis and groin with urination.

Should I be Screened?
“Screening” means testing for a disease even if you have no symptoms. The choice to be screened for prostate cancer is a personal one, and it should be taken seriously. It begins with a conversation with your doctor about your risk for the disease, including your personal and family history. Then, a talk about the benefits and risks of testing.

Generally, screening is recommended for men with no symptoms who are between the ages of 45 to 69. Some men who are at higher risk for prostate cancer should consider screening as early as age 40-45. This group includes African American men and men with a father, brother or son who has had prostate cancer.

What are the Screening Tests for Prostate Cancer?
• Prostate-Specific Antigen (PSA): is a blood test to measure this protein found in the prostate. When screening for prostate cancer, doctors should use PSA as the first screening test.

– A low PSA score is a sign of a healthy prostate.
– A rapid rise in scores may signal a problem (not necessarily cancer).

• Digital Rectal Exam (DRE): is an optional physical test to feel the prostate for problems.

• Biopsy: tests are used if the PSA and/or DRE tests results cause concern. A biopsy is when a tissue sample is removed from the prostate and reviewed under a microscope to detect any cancer cells for a diagnosis.
What are the Signs and Symptoms of Prostate Cancer?

Early stages may cause no symptoms.

Intermediate stages may cause urinary problems like:
- trouble urinating or a weak urine flow
- frequent urination
- pain or burning

Non-cancerous problems (like Prostatitis and BPH) may also cause these symptoms.

High-risk stages cause urinary problems and may include:
- Dull pain in the pelvic area
- Blood in the urine
- Painful ejaculation
- Pain in hips, lower back or upper thighs
- Loss of appetite and/or weight loss

Non-cancerous problems (like Prostatitis and BPH) may also cause these symptoms.

What are the Possible Risks of Biopsy and Treatment?

Biopsies (a surgical procedure to confirm a cancer diagnosis) can cause bleeding or lead to infection. Treating prostate cancer with surgery, radiation, drugs or hormones can cause problems. Most common side effects are erection problems, urine leaks and/or bowel issues. Men must balance the risks of treatment versus the risks of cancer. A slow-growing cancer, for example, may need no treatment at all, especially for older men.

About the Urology Care Foundation

The Urology Care Foundation is the world’s leading urologic foundation – and the official foundation of the American Urological Association. We provide information for those actively managing their urologic health and those ready to make health changes. Our information is based on the American Urological Association resources and is reviewed by medical experts.

To learn more, visit the Urology Care Foundation’s website, UrologyHealth.org/UrologicConditions or go to UrologyHealth.org/FindAUrologist to find a doctor near you.
