What is Vesicoureteral Reflux?

Normally, urine flows one way, down from the kidneys, through tubes called ureters, to the bladder. But what happens when urine flows from the bladder back into the ureters? This is called vesicoureteral reflux (VUR).

With VUR, urine flows backward from the bladder, up the ureter to the kidney. It may happen in one or both ureters. There is a grading system for reflux that goes from one to five. Grade five is the most severe. When the “flap valve” doesn’t work and lets urine flow backward, bacteria from the bladder can enter the kidney. This may cause a kidney infection that can cause kidney damage.

When the reflux is more severe, the ureters and kidneys may become large and winding. More severe reflux is tied to a greater risk of kidney damage if there is an infection present.

How Does the Urinary Tract Work?

Urine is made when blood is filtered by the kidneys. Urine flows from the kidneys down through the ureters and into the bladder. This one-way flow is usually maintained by a “flap valve” where the ureter joins the bladder. This “flap valve” does not look like one you would see on a pipe but it works in a similar way, keeping urine from backing up into the kidney.

What Causes VUR?

The exact percentage of children with VUR is unknown. Estimates are that VUR occurs in about one of every 100 healthy children. It is not contagious. In most children, reflux is the result of a birth defect. There is a shorter than normal attachment between the ureter and bladder or “flap valve” that does not work. While some children are born with reflux, some children may develop it because they do not pass urine properly.

In many cases, reflux appears to be passed down (inherited). About one in three sisters and brothers of children with reflux also have this health problem. Also, if a mother has been treated for reflux, as many as half of her children may also have reflux.

Signs to Look For

</table>

How Is VUR Treated?

VUR is treated either non-surgically, or surgically. A urologist can help guide a patient’s family to the best choice.

- The goal of non-surgical treatment is to prevent UTI and kidney damage while your child grows. Often, reflux gets better without treatment. During the “watch and wait”
period, some doctors offer a long-term, low-dose antibiotic.

• The goal of surgery is to cure reflux and avoid kidney damage. There are a few surgical options. These include an “open” operation, endoscopic injection and robotic laparoscopic surgery.

After VUR treatment, your child should feel much better. You may be asked to see your urologist for follow-up exams to make sure all is well.

To keep healthy, it is of great value to prevent or quickly treat future UTIs. Treating infections quickly will lower the risk of kidney scarring. Some urologists may suggest that infant boys become circumcised to lower your risk of infections.

Questions to Ask Your Doctor

- How did my child develop VUR?
- What treatment do you suggest?
- Is there anything I can do to help my child feel better?
- How will I know if my child is getting better or worse?
- How soon should my child feel better?
- If surgery is best: why and what type?
- How long will it take to recover from surgery?
- How often should I take my child for check-ups?

About the Urology Care Foundation

The Urology Care Foundation is the world’s leading urologic foundation – and the official foundation of the American Urological Association. We provide information for those actively managing their urologic health and those ready to make health changes. Our information is based on the American Urological Association resources and is reviewed by medical experts. To learn more, visit the Urology Care Foundation’s website, UrologyHealth.org/UrologicConditions or go to UrologyHealth.org/FindAUrologist to find a doctor near you.
